²Environmental Research Division, Southwest Fisheries Science Center, NOAA, Monterey, CA, USA

13

14 **Figure S1: Environmental data.** Scatter plots of all data points used in the surface fits of Figs.

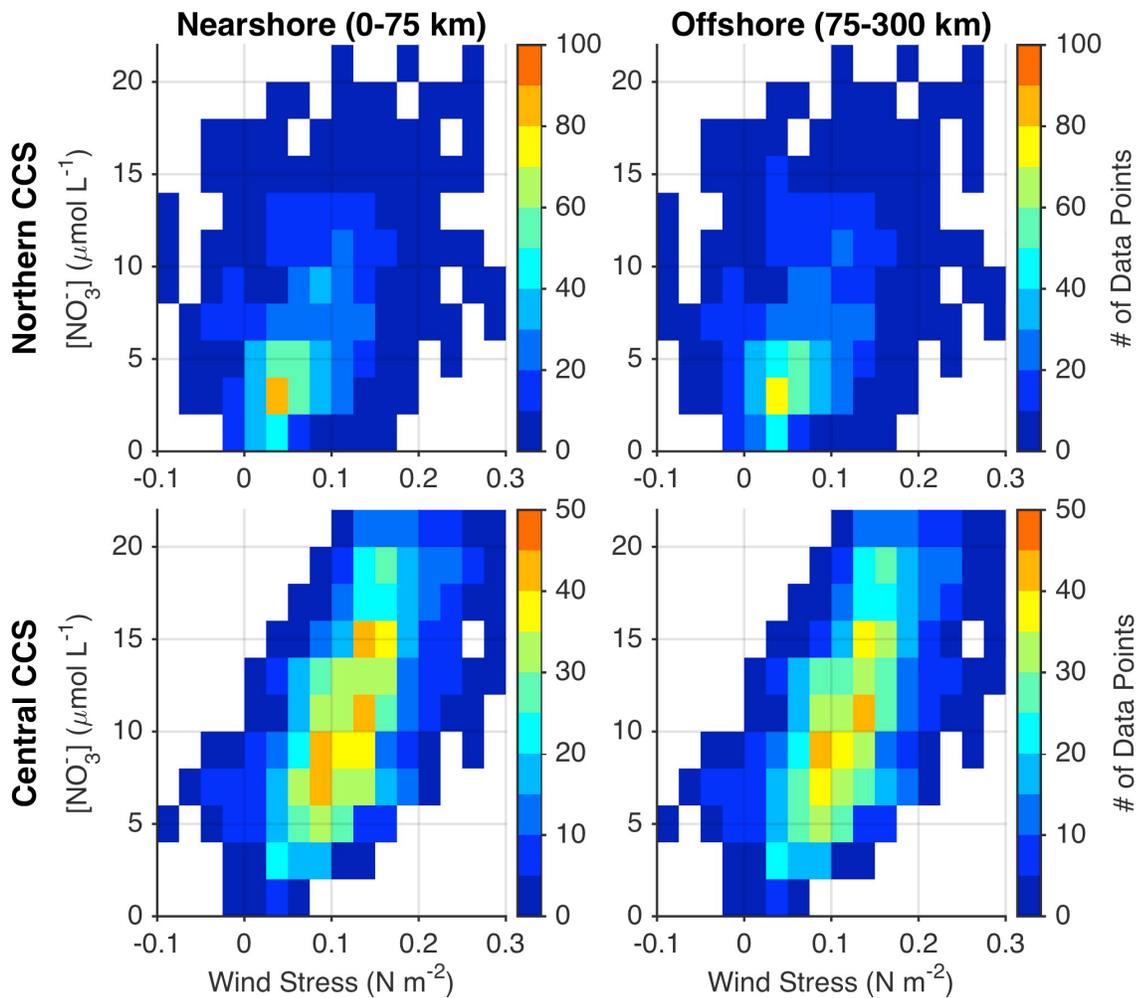

15 2 and 3, one for each region (nearshore/offshore regions of the northern/central CCS). Each data

16 point represents concurrent alongshore wind stress, nitrate concentration at the base of the mixed

17 layer, and surface chlorophyll concentration, produced from 8-day means with a subsequent 3-

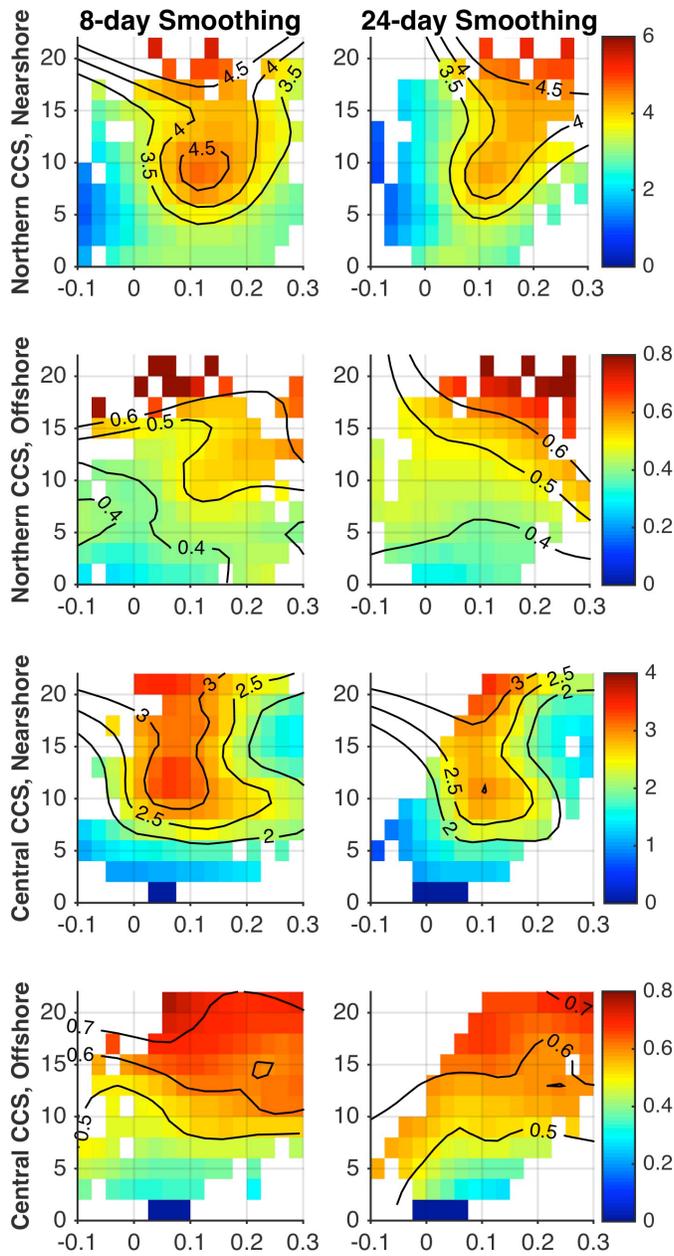

18 point moving average (see Methods).

19

20

21 **Figure S2: Distribution of Environmental data.** For each region, color indicates the number of
 22 data points (from Fig. S1) that fall within each grid cell in the parameter space used for fits in
 23 Figs. 2 and 3. Note that the nearshore and offshore plots are nearly identical as they use the same
 24 wind stress and nitrate data and differ only in the number of data points that are excluded due to
 25 insufficient chlorophyll coverage in each of respective regions.

26

27 **Figure S3: Effect of temporal smoothing on wind-nitrate-chlorophyll fits.** Chlorophyll fit as

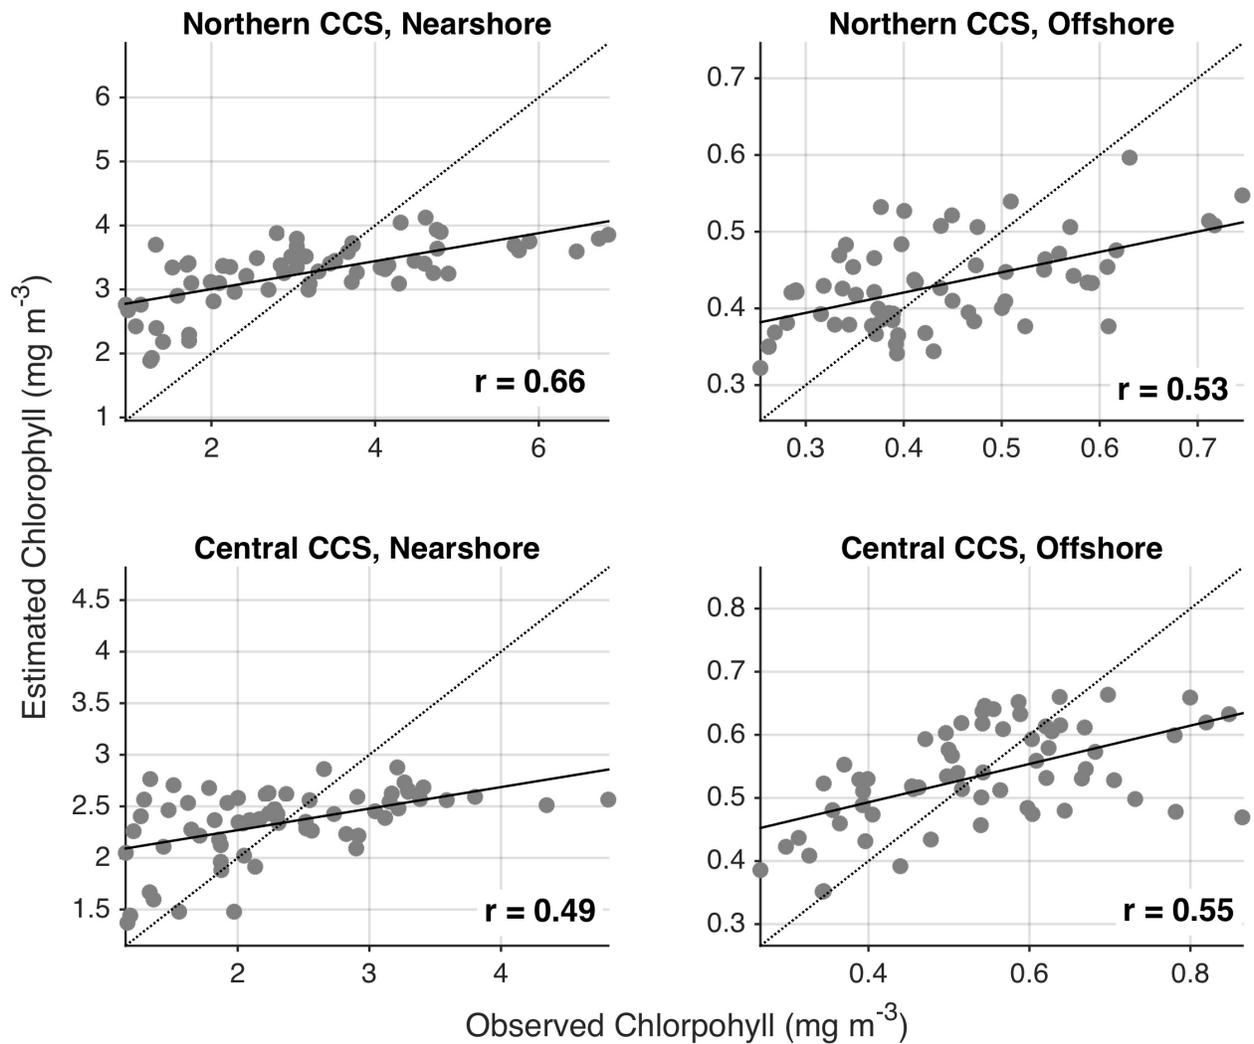

28 a function of wind stress (N m^{-2} , x-axis) and nitrate concentration at the base of the mixed layer

29 ($\mu\text{mol L}^{-1}$, y-axis) is shown before and after applying a 3-point moving average to the 8-day

30 average data. Note that panels in the right column correspond with, from top to bottom, Fig. 2a,

31 3a, 2d, and 3d. Smoothing was applied to reduce unrealistic structure in regions of limited data

32 availability (e.g., the feature at high wind stress and $\sim 10 \mu\text{mol L}^{-1}$ for the nearshore central CCS).

33

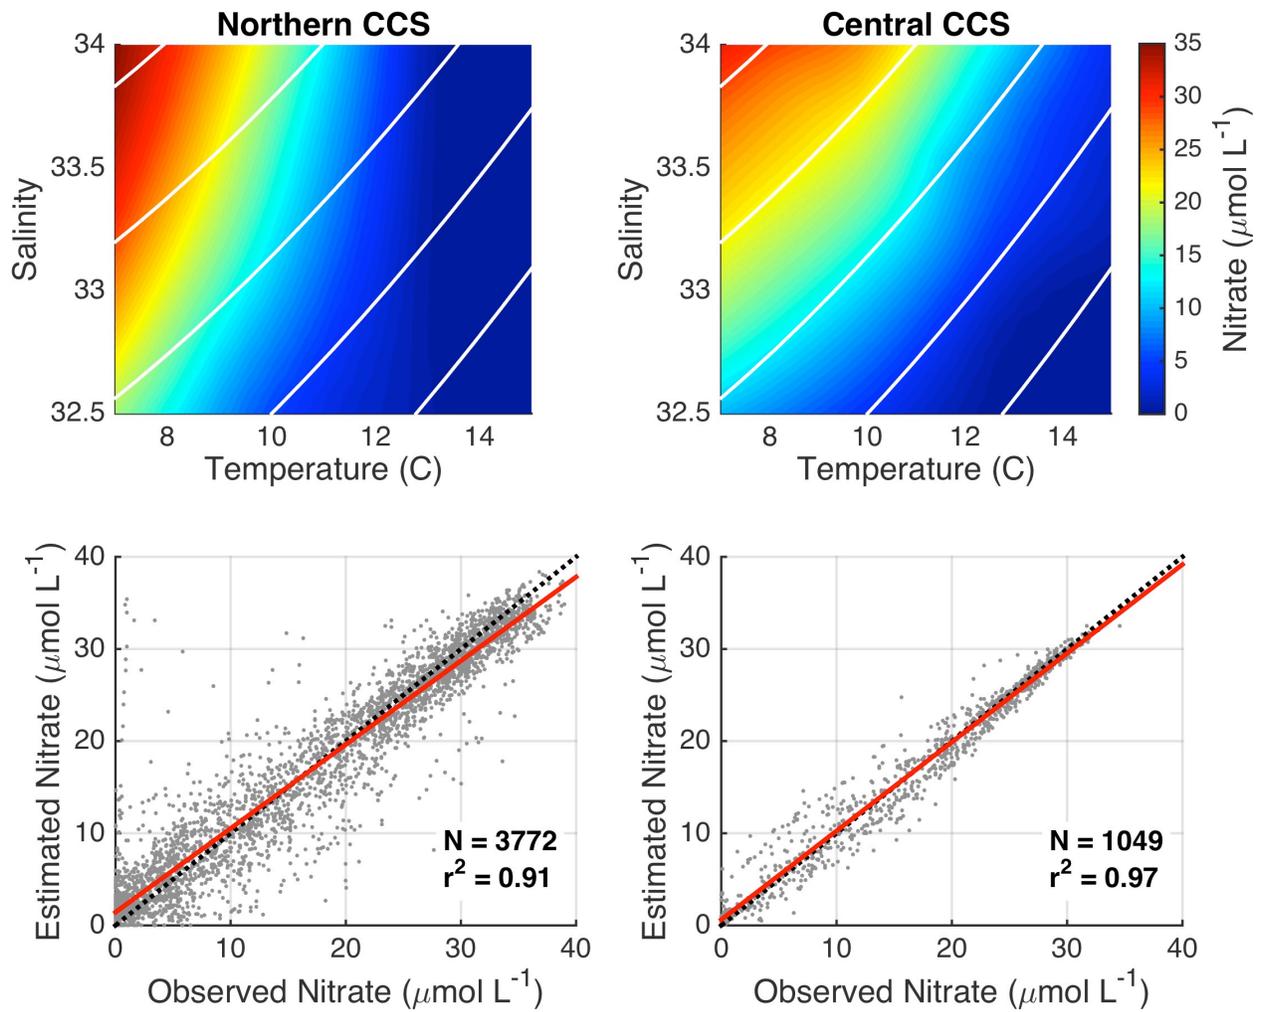

34

35

36

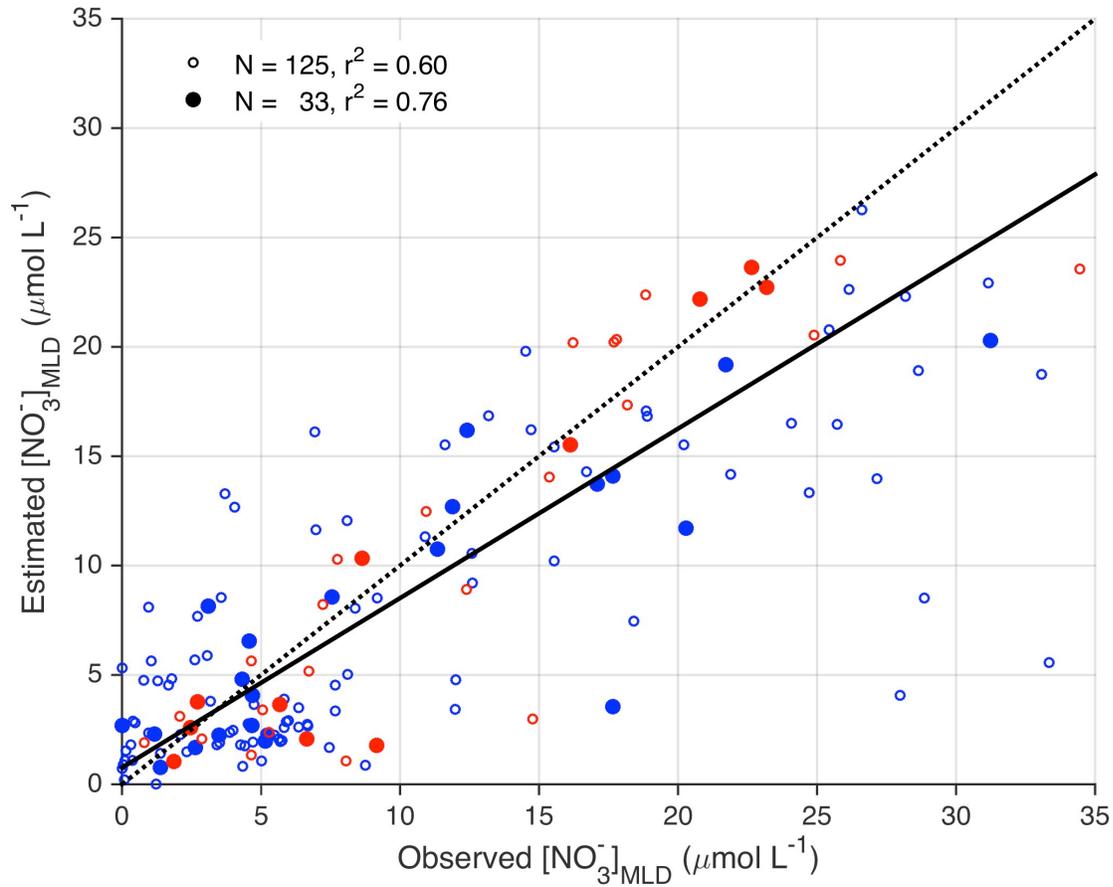

37

Figure S4: Monthly chlorophyll predictions vs. observations. Monthly chlorophyll predictions based on model wind and nitrate estimates and the framework of Figs. 2 and 3. Only months from the upwelling season are included. Note that chlorophyll predictions considerably underestimate the observed variance.

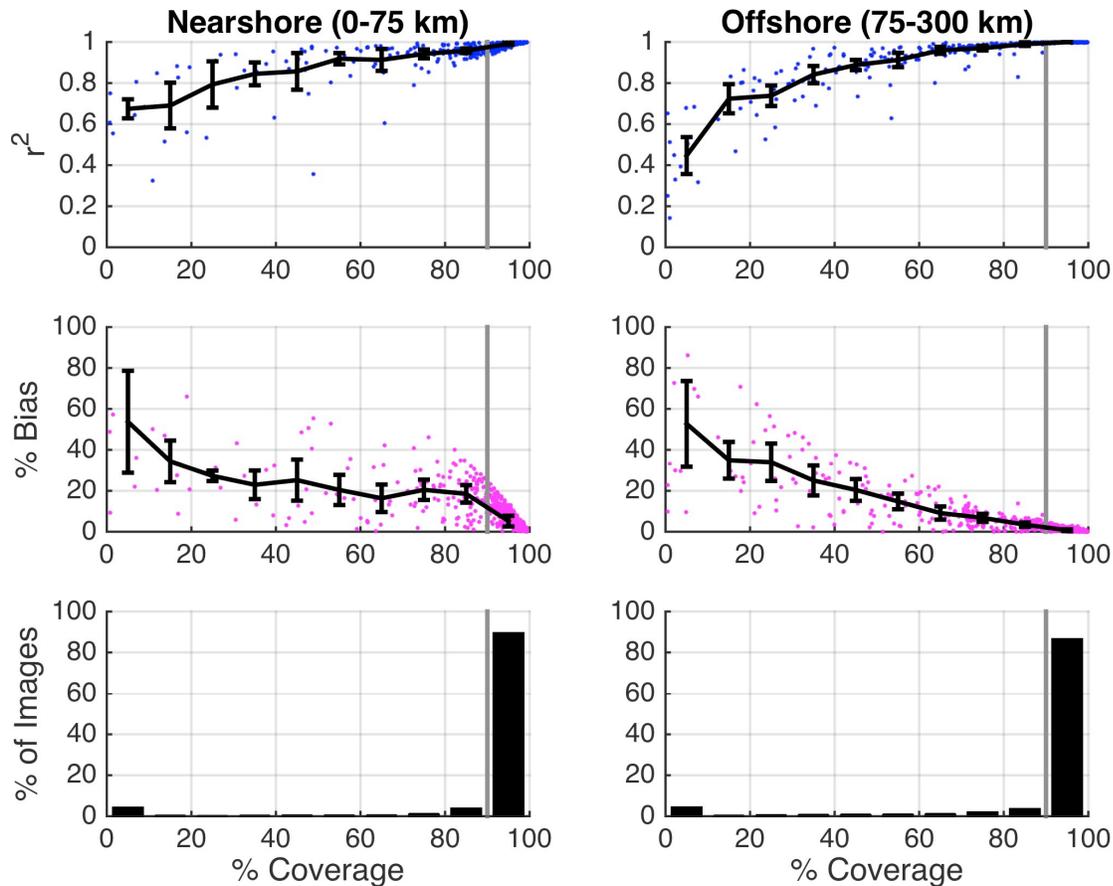

38

39 **Figure S5: Nitrate model.** (top) Temperature-salinity-nitrate relationships and (bottom)
 40 modeled vs. observed nitrate concentrations are shown for the northern and central CCS regions.
 41 Gray dots represent individual measurements, red lines are linear fits, and perfect agreement is
 42 marked by the dotted black 1:1 line.

43

44 **Figure S6: Validation of nitrate estimates.** Available observational data was divided into
 45 northern (blue) and central (red) CCS regions and split 60/40 into training and validation
 46 datasets. Training data was used to produce temperature-salinity-nitrate fits as in Fig. S4.
 47 Validation data was then used to independently estimate nitrate at the base of the mixed layer
 48 from observations and from the model (using the nearest grid cell and time step). Open circles
 49 represent individual casts, while filled circles are averages of casts taken on the same day in
 50 close proximity (e.g., multiple nearshore stations of a CalCOFI line). The latter are more relevant
 51 for the spatially and temporally averaged data used in our analysis. The dotted black line is 1:1
 52 while the solid line is a linear fit to the data.

53

54 **Figure S7: Impact of gaps in chlorophyll data on regional averaging.** For each 1° latitude bin

55 from 34.5°N to 46.5°N, we extract all upwelling season images (8-day means with subsequent 3-

56 point moving average) with no data gaps and create a “cloud-free” time series. For the images

57 with data gaps, we use each one to create a distinct cloud mask, and apply that mask to the

58 cloud-free time series to create an “artificially cloudy” time series. Regional chlorophyll

59 averages are then computed from the “cloud-free” and “artificially cloudy” time series, and their

60 comparison yields one data point in the r^2 and bias plots. The number of data points in each panel

61 is therefore the total number of chlorophyll images with incomplete spatial data coverage. Black

62 lines and vertical bars indicate means and standard deviations, respectively, in 10% bins of

63 coverage. Histograms at bottom show the distribution of data coverage in chlorophyll fields. The

64 vertical gray line marks the 90% cutoff below which data are excluded from the analysis.
